# Discovering new DNA gyrase inhibitors using machine learning approaches†

Long Li,; a Xiu Le,; Ling Wang,; bc Qiong Gu,; a Huihao Zhou; and Jun Xu; and Jun Xu;

Bacterial DNA gyrase is not expressed in eukaryotes. It is a promising target for broad-spectrum antibiotics. This paper reports new DNA gyrase inhibitors as broad-spectrum antibacterial agents discovered by means of target-based *in silico* and *in vitro* models. Two machine learning methods (naïve Bayesian and recursive partitioning) were employed to build *in silico* models based on physicochemical descriptors and structural fingerprints. For both training and testing sets, the overall predictive accuracies of the best *in silico* models were greater than 80%. The best 11 models were used to virtually screen a molecular database to identify DNA gyrase inhibitors. The *in vitro* models were used to verify the virtual hits activities against *Escherichia coli*, methicillin-resistant *Staphylococcus aureus* and other bacteria, and DNA gyrase. The MIC values of the confirmed DNA gyrase inhibitors range between 1 and 32  $\mu$ g mL<sup>-1</sup> and, the relative inhibition rates of the inhibitors range between 42% to 75% at 1  $\mu$ M. Cell-based cytotoxicity assays demonstrated that the confirmed DNA gyrase inhibitors were not toxic. *In silico* studies indicated that the new DNA gyrase inhibitors have similar binding modes to the reported inhibitors.

### 1. Introduction

Growing multidrug-resistant bacteria and declining available antibacterial agents are threating public health. <sup>1-3</sup> New agents against drug-resistant bacteria are demanded. <sup>4,5</sup> DNA gyrase is a promising antibacterial drug target because it is required for all bacteria, and is absent in eukaryotes. DNA gyrase is a type II topoisomerase that mediates negative supercoiling to relaxed closed circular DNA<sup>6,7</sup> and is well-studied as an anti-bacterial target. <sup>8,9</sup> However, only one compound (ETX0914) is in clinical trials. Others DNA gyrase inhibitors are failures due to side effects or poor bioavailability.

DNA gyrase is a hetero tetramer made up of two GyrA and two GyrB subunits.<sup>8</sup> GyrA consists of two stable fragments GyrA33 and GyrA64.<sup>10</sup> GyrA64 catalyzes supercoiling reaction while the GyrB exists and, associates with DNA cleavage and ligation under the condition of holoenzyme. GyrA33 directly effects on DNA and

‡ The experiment design JX, LL, XL, LW. Implementation: LL, HZ, QG. Manuscript revision and submission: LL and JX.

forms DNA-enzyme complex that catalyzes supercoiling reaction together with GryA64 and GyrB.<sup>11,12</sup> In the same way, GyrB consists of fragments GyrB43 and GyrB47. The N-terminal of GyrB43 hydrolyses ATP. As a part of GyrB43, GyrB24 binds DNA gyrase inhibitors such as novobiocin,<sup>13</sup> aminocoumarin<sup>13,14</sup> and cyclothialidine;<sup>15,16</sup> the C-terminal GyrB47 catalyzes supercoiling DNA to relaxed DNA in the presence of GyrA (Fig. 1).<sup>17,18</sup>

DNA gyrase inhibitors (such as, GSK299423, NXL101 and gyramide) contain either have quinolone scaffold (A)<sup>19,20</sup> or aminocoumarins scaffold (B)<sup>21</sup> (Fig. 2). Quinolones may inhibit supercoiling activity or, induce DNA double-strand breaking. As examples of scaffold A, fluoroquinolones (FQ) are bacterial topoisomerase inhibitors.<sup>22</sup> The aminocoumarins (such as aminopyrazinamides, hiazolopyridine ureas, and pyrrolamides) are the competitive inhibitors of ATP hydrolysis, and inhibit DNA supercoiling activities.<sup>23–25</sup>

So far, only three anti drug-resistant bacteria agents (daptomycin, linezolid and bedaquiline) were reported since 1960. DNA gyrase (an anti drug-resistant bacteria drug target) has only one compound (ETX0914), which is under phase II clinical trials.<sup>25</sup> It is demanded for new DNA gyrase inhibitors. Known DNA gyrase inhibitors have diverse scaffolds (Fig. 3), which mean that the active sites of the target can adopt diversified ligand shapes. The relations between structures and DNA gyrase inhibitory activities cannot be assumed as being linear or other continuous functional. Hence, we employ two machine learning approaches, naïve Bayesian (NB) learning and recursive partitioning (RP) approaches to generate virtual screening models from target-based DNA gyrase inhibitory data.<sup>26</sup> To assure the robustness of the models, we evaluated the models by means of 5-fold cross validations. An external testing

data set was also used to test the models. Then, the models were used to virtually screen an in-house compound library, which consisted of 488 tangible compounds.<sup>27,28</sup> The virtual hits were validated with cell-based and target-based microbial assays, and following with cytotoxicity assays. The binding modes of confirmed DNA gyrase inhibitors were investigated.

#### Materials and methods

#### 2.1 Data for generating virtual screening models

The DNA gyrase inhibitor bioassay data were extracted from the ChEMBL<sup>29</sup> and BindingDB databases by taking target-based *Escherichia coli* strain bioassay data. Duplicated records or records without IC<sub>50</sub> values were removed. This resulted in 137 DNA gyrase inhibitors with IC<sub>50</sub> values ranging from 0.9 to 1 000 000 nM. These compounds were categorized into positives and negatives based upon their IC<sub>50</sub> values (the compounds with IC<sub>50</sub> values less than or equal to 5  $\mu$ M were marked with "1" for positives. Others were marked with "0" for negatives). The entire data set was randomly divided into four portions. A training set was made of the three portions containing 103 compounds. The remaining portion was used as a testing set containing 34 compounds.<sup>30</sup> This process was done with DS (Discovery Studio 3.5, Accelrys, San Diego, USA). The detailed process can be examined in ESI.†

#### 2.2 Molecular descriptor calculation and selection

The molecular descriptors of the data set were computed with MOE 2013.08 (CCG, Montreal, Canada) and DS, resulting in 192 MOE molecular descriptors and 252 DS molecular descriptors for each compound in the data set.

With Pearson correlation analyses, the redundant molecular descriptors (selective ratio > 0.9) were removed, the molecular descriptors (selective ratio < 0.1), which were unrelated to the DNA gyrase inhibitory activities, were excluded.<sup>27,28,31</sup> This resulted in 36 MOE descriptors and 15 DS descriptors (Table 1).

#### 2.3 Structural fingerprints calculation

Structural fingerprints were calculated using DS software. The fingerprints consist of daylight-style path-based fingerprints and SciTegic extended-connectivity fingerprints.

#### 2.4 Machine learning approaches

Two machine learning methods, NB and RP, were applied through DS software.

**2.4.1 NB method.** NB method is a supervised learning approach, and directly calculates the overall distribution based on the prior distribution of parameters and the posterior distribution of parameters obtained from the sample data. The method is based on the Bayes' theorem and the maximum posteriori hypothesis,<sup>32</sup> requires the training objects are marked with positives or negatives.<sup>33</sup>

**2.4.2 RP method.** RP (or decision tree) is a statistical method for multivariable analysis and, based on hierarchical rules. It creates a decision tree to describe the relationship between an active and a set of properties/descriptors of objects.<sup>34,35</sup>

#### 2.5 Decoys generation

The decoy data were generated from DUD-E<sup>36</sup> (http://dude.docking.org/) through the Pipeline Pilot 7.5 module of DiscoveryStudio. 10 diverse compounds were used as reference compounds, which were randomly selected from the positives in the input data set. The decoys were selected from DUD-E based upon the dissimilarity to the reference compounds. 80 decoys, which were regarded as negatives, were selected for external tests.

#### 2.6 Method for model performance evaluation

A 5-fold cross validation was used to evaluate the performances of NB and RP models. True positives (TP), true negatives (TN), false positives (FP), false negatives (FN), sensitivity (SE), specificity (SP), overall predictive accuracy (Q), the Matthews correlation coefficient (C) and the receiver operating characteristic (ROC) curve were defined as follows to measure the performance:<sup>37</sup>

$$SE = \frac{TP}{TP + FN}$$

$$SP = \frac{TN}{TN + FP}$$

$$Q = \frac{TP + TN}{TP + FN + TN + FP}$$

$$C = \frac{\text{TP} \times \text{TN} - \text{FN} \times \text{FP}}{\sqrt{(\text{TP} + \text{FN})(\text{TP} + \text{FP})(\text{TN} + \text{FN})(\text{TN} + \text{FP})}}$$

#### 2.7 Compound library for virtual screening campaigns

The in-house tangible compound library, which contains 488 natural products or chemically modified natural products, were virtually screened with the best machine learning models.

#### 2.8 In vitro antimicrobial assay

2.8.1 Minimum inhibitory concentration testing. The test was performed to determine the minimum concentration of the indicated agent necessary to inhibit visible growth of bacteria. In this study, our compounds were tested against bacteria including MRSA ST239, MRSA ST5, MRSA 252, Staphylococcus aureus, Fecal bacteria, Staphylococcus epidermidis, Pneumonia, ATCC 25922 and Shigella flexneri. Ampicillin and vancomycin sodium were used as positive control agents. The MIC values were determined using Mueller-Hinton broth method based on national committee for clinical laboratory standard.38,39 Each compound was tested for 11 concentrations (256, 128, 64, 32, 16, 8, 4, 2, 1, 0.5, 0.25  $\mu g \text{ mL}^{-1}$ ). 90 µL bacterial culture medium was added into the first column of wells of flat bottomed 96-well tissue culture plates, and other wells were added with 50 µL same medium, and then 10 µL solution of compound was added into the first column of wells. Then, 50 µL mixture extracted from the first column wells were transferred to the second column of wells, and repeated this operation column by column till the second last column of wells. After this step, the 50  $\mu$ L bacterial culture solutions in last column of wells were discarded. Finally, 50 μL bacterial solution was diluted by culture medium, and added into all wells in the 96-well plate. The last row wells were for positive controls, and the last column wells were for negative controls. The plates were incubated at 37 °C overnight in electro-heating standingtemperature cultivator before the measurement of the absorbance value. We used a multifunction microplate reader to measure the optical density values at 600 nm. Each antimicrobial assay was replicated four times.

#### 2.9 DNA gyrase expression and purification

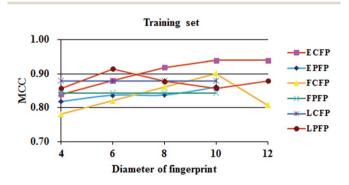

The recombinant protein was expressed with plasmids pET-15-GyrA and pET-15b-GyrB in *E. coli*, and purified using Ni-NTA column. After the SDS-PAGE verification, we mixed GyrA and Gry B at 1 : 1 molar ratio, and incubated on ice for 30 min before DNA supercoiling assay.<sup>39</sup>

#### 2.10 DNA gyrase-mediated pHOT-1 supercoiling assay

The DNA supercoiling assay was conducted to test the inhibitory activity on the enzyme reaction. Firstly, 4  $\mu L$  5  $\times$  DNA gyrase assay buffer, 0.1 U relaxed pHOT-1 DNA and 12.9  $\mu L$  ddH $_2 O$  were mixed. Then, 17  $\mu L$  mixture mentioned above, 2  $\mu L$  compounds and 1  $\mu L$  reconstituted DNA gyrase were mixed, and incubated at 37 °C. After 1 h, 4  $\mu L$  5  $\times$  stop buffer was added to stop the reaction. Novobiocin was used as positive control, and 1% DMSO was employed as blank control. To separate the DNA products, electrophoresis on a 1% agarose gel run used. The gel was stained for 20 min in ethidium bromide, decolored for 15 min in water and visualized with UV light. The optical density of the bands for supercoiling and relaxed DNA was quantified using the Quantity One software. The inhibition rates were used to calculate the IC $_{50}$  values with GraphPad Prism 5. The IC $_{50}$  values were measured with 7 concentration points, and repeated for three times.

#### 2.11 Cytotoxicity assay

HEK-293, a human embryonic kidney normal cell line, was used to evaluate the cytotoxicity of the compounds. HEK-293 cells were inoculated in 96-well plates with DMEM medium containing 10% fetal bovine serum at 37 °C in 5% CO $_2$  incubator. Then, the cells were intervened with different compounds at 20  $\mu$ M for 24 h after cells were adherent and each compound was added into three parallel double wells. Blank control group and empty wells were prepared. Then 20  $\mu$ L 2.5 mg mL $^{-1}$  MTT was added to each well and incubated for 4 h, and 100  $\mu$ L DMSO was added every well lastly. Absorption values were measured at 492 nm after 20 minutes' oscillation. The inhibition rate of each compound against 293T cell lines was calculated with the following formula: inhibition of cell (%) = 1 -  $(A_{\rm experimental group}$  -  $A_{\rm blank})/(A_{\rm control group}$  -  $A_{\rm blank})\times$  100%.40

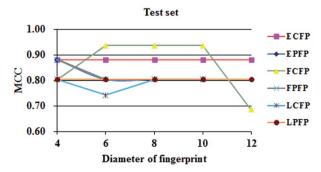

Fig. 4 The relations among MCCs and fingerprint sizes or types.

#### 2.12 Molecular docking

The intact DNA gyrase (PDB code: 3G7E)<sup>25</sup> was used as the template to explore the binding modes of the confirmed DNA gyrase inhibitors. The structure data was processed using a protocol from Schrödinger software 2013.01 (Schrödinger Inc., New York, USA). The active compounds were prepared by Ligprep module in the Schrödinger software. The extra precision Glide 5.9 (ref. 41–43) of Schrödinger software was used to dock the active compound structures into the binding pocket of the DNA gyrase. The active compounds were also superimposed with the native ligand using WEGA algorithm<sup>44</sup> to ensure the correct docking pose.

## 3. Results

# 3.1 Classifiers derived from molecular descriptors or structural fingerprints

Fig. 4 indicates that the size (the diameter of a fingerprint) of a structural fingerprint or the type (ECFP, *etc.*) of a structural fingerprint can change the model performance (MCC value). But, there is no general trend. SciTegic extended-connectivity fingerprints resulted in better performance in general.

Table 2 lists the performance parameters of top-10 machine learning models running on training set and testing set. The top-10

models were all generated from NB method with overall predictive accuracies greater than 94.1% for both training set and test set. For the testing set, the models using FCFP\_6, FCFP\_8 and FCFP\_10 fingerprints achieved better performances with the sensitivity of 95.4%, the specificity of 100.0%, overall prediction accuracies of 97.1%, and the AUC value of 0.992.

combined molecular descriptors and structural fingerprints can result better performance than the ones of using non-combined descriptors or fingerprints.

#### 3.3 Determining and external testing final models

Combining Tables 2 and 3, we get top-11 models after removed duplicated models. The 11 final models were tested with the external testing data set. Table 4 lists the results.

The overall prediction accuracies of the final models are greater than 80% (except models FCFP\_6, MOE+EPFP\_4). The top model (FCFP\_10) was generated from NB method (see the first row in Table 4).

# 3.4 Virtual screening DNA gyrase inhibitors with the final models

Our in-house library, which has 488 tangible compounds, was virtually screened with the top-11 predictive models (Table 4), which consist of nine NB models, and two RP models. The NB models resulted in 67 hits, and the RP models resulted in 19 hits. By combining the two hit sets, we got 76 initial hits without duplicates. The initial hits were further refined by scaffold analyzing processes, which removed known antibacterial scaffolds (such as, flavone derivatives), and resulted in 24 refined

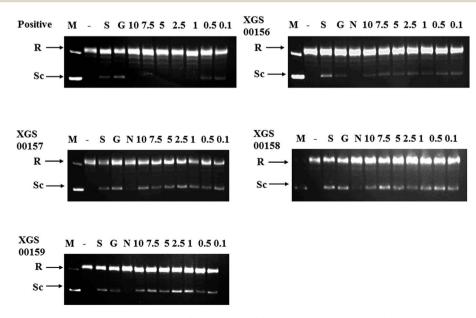

Fig. 7 DNA supercoiling assay results for the 4 compounds (XGS00156, XGS00157, XGS00158 and XGS00159). R: relaxed DNA; Sc: supercoiled DNA; M: marker; —: negative control; S: activity of enzyme; G: 1% DMSO; N: positive control, novobiocin.

RSC Advances Paper

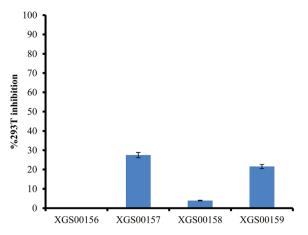

Fig. 8 Cytotoxicity assay results.

hits. These refined hits were tested with cell-based microbiological assays. The flow-chart of discovering new DNA gyrase inhibitors using machine learning approaches is depicted in Fig. 5.

#### 3.5 Cell-based microbiological assay results

Both G+ and G- strains were tested in the cell-based microbiological assays. Ampicillin sodium and vancomycin sodium

were used as positive controls. 4 compounds actively inhibited  $E.\ coli$  and MRSA strains (XGS00156, XGS00157, XGS00158 and XGS00159). As shown in Table 5, the 4 active compounds have MIC values < 10  $\mu$ M. The advantages of the 4 compounds are that these compounds exhibited broader spectrum of antibacterial activities than ampicillin or vancomycin. The activities of compound XGS00159 are comparable with the ones of ampicillin or vancomycin. All active compounds share the same scaffold. Their initial SAR is established (Fig. 6).

#### 3.6 DNA supercoiling assay results

The 4 compounds were tested with DNA supercoiling assays. Novobiocin was used as a positive control. The results were depicted in Fig. 7, and indicated that the 4 compounds dose-dependently inhibited DNA supercoiling. Thus, the 4 compounds have been proved that they are DNA gyrase inhibitors.

#### 3.7 Cytotoxicity assay results

Fig. 8 depicts the cytotoxicity assay results for the 4 active compounds. At 20  $\mu$ M, two active compounds inhibited <5% of 293T cell lines, other two compounds inhibited <30% of 293T cell lines. Thus, the 4 active compounds are considered as promising drug leads, and worth further lead optimization processing.<sup>40</sup>

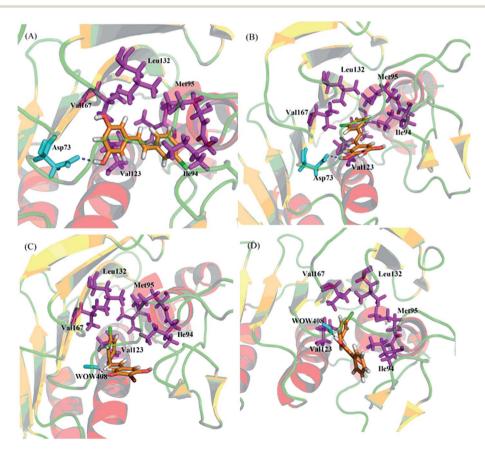

Fig. 9 Molecular docking study results. (A): Binding mode of XGS00156; (B): binding mode of XGS00157; (C): binding mode of XGS00158; (D): binding mode of XGS00159. The molecules in orange are the active compounds; the residues in blue donor hydrogen bonds; the residues in red provide hydrophobic interactions. The deep blue dashed lines represent hydrogen bonds.

#### 3.8 Molecular docking study results

The 4 compounds were docked to the crystal structure (3G7E), in which the native ligand was removed. The docking processes were executed with both the extra precision Glide and WEGA algorithm. The docking poses of the compounds were consistent. This demonstrated that the docking processes were reliable. Fig. 9 depicts the binding modes of the 4 active compounds. All 4 compounds have the similar interactions with the known key residues, such as WOW 408 or Asp 73, which is a hydrogen bond donor. The hydrophobic groups of the compounds interact with the receptor hydrophobic pocket (Val 43, Met 95, Ile 94, Val 123, Leu 132 and Val 167). 45,46 Thus, these active compounds binding modes support the observations of the *in vitro* results.

#### 4. Conclusions

DNA gyrase is a promising drug target, but, there are not many DNA gyrase inhibitors under clinic trails. Existing DNA gyrase inhibitors are structurally diverse, it would be difficult to discover novel DNA gyrase inhibitors through structure-based molecular design, or individual ligand-based modeling technology, or traditional QSAR techniques. This work demonstrates that we can discover a novel scaffold of DNA gyrase inhibitors by combining multiple machine learning methods and target-based approaches. There are many ways to build virtual screening models due to many types of structural descriptors or fingerprints. Since we did not discover specific descriptors or fingerprints were particular superior to the others for the virtual screening campaign. To do our best to include excellent virtual screening models, we have explored 424 machine learning models derived from the combinations of the descriptors or fingerprints. The confirmed hits were generated from the top-11 models.
